KEY INSIGHTS

- This dataset comprises detailed clinical, physiological and historical health information collected from maternal patients to evaluate potential risks during pregnancy
- The fact that many individuals with hypertension do not fall into high risk categories confirms that the condition is multifactorial
- Even though this dataset's risk classification is a multifactorial, there are some potential factors which we must address to support maternal health patients. Mental health is a primary concern ,70% of high risk pregnancy patients experience mental health issues .Care must be provided by both families and healthcare professionals.
- Elevated blood sugar values (>9mmol/L) often correlate with high risk labels. Presence of gestational diabetes or preexisting diabetes strongly increases the chance of being marked high risk
- BMI extremes (very high or very low) are also associated with high risk
- Age and Body temperature appear to have limited impact on risk classification
